1. Technical Field The present invention relates to a piezoelectric device, a drive circuit, a display device, and an electronic apparatus. 2. Related Art There is a known technique of driving a piezoelectric device in a contact mode in which a piezoelectric device is brought into contact with a target object to apply pressure, a force with which the piezoelectric device is pressed against the target object is controlled, and deformation is thus generated in the target object. The piezoelectric device in the contact mode is sometimes referred to as a pyroelectric sensor. As for the piezoelectric device in the contact mode, a piezoelectric device which detects vibration with high sensitivity can be implemented in which a piezoelectric device is brought into contact with a target object and is then detached from the target object after a specified vibration is generated (for example, see JP-A-2012-137143). Such a piezoelectric device in the contact mode is typically operated by a drive circuit in which the piezoelectric device is connected between a power supply and a reference potential (for example, see JP-A-2003-31107). The drive circuit in the piezoelectric device in the contact mode is used, for example, for a piezoelectric actuator used for an inkjet printer, a piezoelectric actuator used for an injection molding machine, or the like. A piezoelectric device in the contact mode is generally driven in the contact mode in which a target object is brought into contact with the piezoelectric device and the target object is then detached from the piezoelectric device. In the piezoelectric device in the contact mode, a target object to be driven (referred to as a driven target object hereinafter) is deformed with a driving force which is a combination of a force which is generated by a piezoelectric device.
