[Confirmation of the six susceptibility loci for tuberculosis in Chinese Han population and assessment of their effects]. To confirm the six susceptibility loci in Chinese Han population for tuberculosis (TB) and evaluate the effects of these loci. A total of 1502 unrelated Chinese Han subjects including 742 tuberculosis patients and 750 healthy controls were enrolled in this study. The six susceptibility loci (IL23R, IFNG, ERBB3, IL12B, PTPN22 and IFNGR1) were genotyped by TaqMan PCR-based allelic discrimination assay. The associations between the loci and the risk of TB were investigated by logistic regression analysis. The frequencies of the genotypes of IL23R -719T/A and IFNG -148G/A were different between TB patients and healthy controls ($\chi^2 = 7.59$, $P = 0.006$; $\chi^2 = 6.49$, $P = 0.01$), respectively. The OR of TB for the genotypes of A/A and A/G were 4.95 (95% CI: 2.32-10.52) and 1.91 (95% CI: 1.00-3.64), respectively. The frequencies of the alleles of IL23R -719T and IFNG -148A of TB patients were 8.93% and 10.06%, respectively, significantly higher than that of healthy controls (c6a93da74d
